1: Consider a one-way ANOVA design with 5 factors and 10 replicates per factor. Suppose that factor variance $\sigma^2_\tau$ is ten percent of the total variance $\sigma^2_T$ (i.e., $\sigma^2_\tau / \sigma^2_T = 0.10$).

(a) Given that the total variance equals the treatment plus error variance ($\sigma^2_T = \sigma^2_\tau + \sigma^2_e$), what is $\sigma^2_\tau / \sigma^2_e$?

(b) What is the 95% critical value for the F-test?

(c) What is the power of this design (assuming a test of $\alpha = 0.05$) for a fixed-effects ANOVA?

(d) What is the power of this design under a random-effects ANOVA?

(e) Given these sample sizes, what is the smallest value of $\sigma^2_\tau / \sigma^2_e$ that gives a (fixed-effects) 95% test a power of 0.90? (You will need to do this, and some the remaining problems, by trial and error.)

(f) Given these sample sizes, what is the smallest value of $\sigma^2_\tau / \sigma^2_e$ that gives a random-effects 95% test a power of 0.90?

(g) How many replicates per factor are needed to give the fixed-effects ANOVA a power of 90% under a test of significant with $\alpha = 0.05$?

(h) How many replicates per factor are needed to give the random-effects ANOVA a power of 90% under a test of significant with $\alpha = 0.05$?

2: Optimal design for a random-effects ANOVA. Suppose you have a total $T = 100$ measurements that you can make, and you have to decide how best to allocate them over $N$ and $n$ in a random-effects design. Should one chose more factors (increase $N$) at the expense of fewer replicates $n$ per factor? Obviously, there is some intermediate trade-off between the two. Suppose that the factor variance is $\sigma^2_\tau = 10$ and the error variance $\sigma^2_e = 20$.

(a) Compute the power of this design for the following combinations of $N$ and $n$:

\begin{align*}
50,2 & 33,3 & 25,4 & 20,5 & 10,10 & 5,20 & 4,25 & 3,33 & 2,50
\end{align*}

\textit{Hint:} It might make sense to first write an R function to do this for arbitrary $N, n$

(b) What is the optimal design (i.e., which combination of $N$ and $n$ gives the largest power)?

(c) Repeat (a) and (b) assuming $\sigma^2_\tau = 20, \sigma^2_e = 10$
